Abstract

A new transition metal complexes of Mn(II) and Fe(III) were prepared from bidentate Schiff base. The Schiff base ligand synthesized from the condensation of P-chlorobenzaldehyde and 2-amino-4-hydroxy-6-methylpyrimidine (L₅) in alcohol medium. These metal complexes were characterized on the basis of their micro analytical data, molar conductance, magnetic susceptibility, IR, UV-Vis, ¹H NMR, X-ray diffraction, thermogravimetric analysis. The ligand and their metal complexes were screened for fungicidal activity against various fungi like *Aspergillus niger*, *Penicillium chrysogenum*, *Fusarium moneliforme* and *Aspergillus flavus*. The antibacterial activity against various bacteria like *Escherichia coli*, *Salmonellatyphi*, *Staphylococcus aureus*, *B.subtilis*. The result indicated that the complexes exhibited good antifungal and antibacterial activities.

Keywords: Schiff bases, Transition metal complexes, Thermal analysis, Powder X-ray diffraction, Antimicrobial activity.

Introduction

The Schiff bases and their metal complexes have more importance recently [1-5] because of their application as biological, biochemical, analytical, antimicrobial, anticancer, antibacterial, antifungal and anti tumor activity. They have been studied as a class of ligands [6-8] and are known to coordinate with metal ions through the azomethine nitrogen atom. The synthesis of transition metal complexes with Schiff base ligands are studied due to sensitivity, selectivity and synthetic flexibility towards metal atoms [9]. They used as catalyst, in medicine like antibiotics and anti-inflammatory agents and in the industry as anticorrosion [10-16]. A search of literature reveals that no work has been done on the transition metal complexes of the Schiff bases derived from 2-amino-4-hydroxy-6-methylpyrimidine and P-chlorobenzaldehyde. In this communication we report the synthesis of bidentate Schiff bases formed by the condensation of 2-amino-4-hydroxy-6-methylpyrimidine and P-chlorobenzaldehyde (Fig.5). The solid complexes of Mn(II) and Fe(III)

with these ligands have been prepared and characterized by different physico-chemical methods.

Materials and Methods

Reagents and solvents

2-amino-4-hydroxy-6-methylpyrimidine (Aldrich sigma), P-chlorobenzaldehyde, metal nitrate of (AR grade) was used for synthesis of ligand and metal complex.

Synthesis of ligand

The ligand was prepared by a modification of the reported methods [17-19]. The Schiff base ligand has been synthesized by refluxing a mixture of 0.01 mol (1.4057g) of P-chlorobenzaldehyde and 0.01 mol (1.2513 g) of 2-amino-4-hydroxy-6-methylpyrimidine in 50 ml super dry ethanol refluxed for about 4h. Schiff base thus formed was cooled to room temperature and collected by filtration, followed by recrystallization in

ethanol and dried *in vacuo* over anhydrous calcium chloride (Yield:75%).

Synthesis of metal complexes

To a hot ethanol solution (25ml) of the ligand (2 mol) and (25ml) of metal Nitrate (1mol) was added with constant stirring. The pH of reaction mixture was adjusted to 7-8 by adding 10% alcoholic ammonia solution and refluxed for about 3 h. The precipitated solid metal complex was filtered off in hot condition and washed with hot ethanol and dried over calcium chloride in vacuum desiccators. (Yield: 70%)

Physical Measurement

IR spectra were recorded on FTIR (ATR)-BRUKER - TENSOR37 spectrometer using KBr pellets in the range of 4000-400 cm^{-1} . ^1H - NMR Varian mercury 300MHZ spectra of ligand were measured in CDCl_3 using TMS as internal standard. X-RD was recorded on BRUKER D8 Advance. TGA- DTA was recorded on Shimadzu. The carbon, hydrogen and nitrogen contents were determined on Elemental model vario EL-III. The UV-visible spectra of the complexes were recorded on model UV-1800, SHIMADZU spectrometer. Molar conductance of complexes was measured on Elico CM 180 conductivity meter using 10^{-4} M solution in DMSO. Magnetic susceptibility measurements of the metal chelates were done on a Guoy balance at room temperature using $\text{Hg}[\text{Co}(\text{SCN})_4]$ as a calibrate.

Results and Discussion

Schiff bases of 2-amino-4-hydroxy-6-methylpyrimidine and its complexes have a variety of applications including biological, clinical and analytical. The coordinating possibility of 2-amino-4-hydroxy-6-methylpyrimidine has been improved by condensing with a variety of carbonyl compounds. An attempt has been made to synthesize Schiff bases 2-amino-4-hydroxy-6-methylpyrimidine with P-chlorobenzaldehyde. Physical characteristics, micro analytical, and molar conductance data of ligand and metal complexes are given in (Table 1 and 2).The analytical data of complexes reveals 2:1 molar ratio (ligand: metal) and corresponds well with the general formula $[\text{ML}(\text{H}_2\text{O})_2]$ (where M= Mn(II) and Fe(III)). The magnetic susceptibilities of Mn(II) and Fe(III) complexes at room temperature are consistent with high spin octahedral structure with two water molecules coordinated to metal ion. The presence of two coordinated water molecules was confirmed by TG-DTA analysis. The metal chelate solutions in DMSO show low conductance and supports their non-electrolyte nature.(Table 1)

^1H -NMR spectra of ligand

The ^1H -NMR. Spectra of free ligand at room temperature show the following signals. 2.48 (s, 3H, Methyl hydrogen bonded to pyrimidine ring), 3.79 (s, 2H, Phenolic (OH) hydrogen of pyrimidine ring), 5.76 (s, 1H, Hydrogen bonded to pyrimidine ring), 7.95 (s, 1H, hydrogen bonded to azomethine carbon), 7.3-7.6 (D,4H, Aromatic H_a , H_b , protons of phenyl ring).

IR Spectra

The IR spectra of the complexes are compared with that of the ligand to determine the changes that might have taken place during the complexation. The bands at 3473, 1656, 1597, 1356, and 1230 cm^{-1} assignable to ν OH (intramolecular hydrogen bonded), ν C=C(aromatic), ν C=N (azomethine), ν C-N (aryl azomethine) and ν C-O (phenolic) stretching modes respectively[18-20] The absence of a weak broad band in the 3200-3400 cm^{-1} region, in the spectra of the metal complexes suggests deprotonation of the intramolecular hydrogen bonded OH group on complexation and subsequent coordination of phenolic oxygen to the metal ion. This is further supported by downward shift in C-O (phenolic) [21] with respect to free ligand. On complexation, the ν (C=N)[22] band is shifted to lower wave number with respect to free ligand, denoting that the nitrogen of azomethine group is coordinated to the metal ion. The ν C-N band is shifted to lower wave number with respect to free ligand, The IR spectra of metal chelates showed new bands in between the 500-800 and 400-500 cm^{-1} regions which can be assigned to ν M-O and M-N [23] vibrations respectively The IR spectra of Mn(II) and Fe(III) show a strong band in the 3050-3600 cm^{-1} region, suggesting the presence of coordinated water in these metal complexes. The presence of coordinated water is further confirmed by the appearance of non-ligand band in 830-840 cm^{-1} region, assignable to the rocking mode of water. The presence of coordinated water is also established and supported by TGA/DTA analysis of these complexes. Hence it is concluded that the coordination takes place via phenolic oxygen and azomethine nitrogen of ligand molecule.

Thermogravimetric analysis

The dynamic TGA with the percentage mass loss at different steps have been recorded. The simultaneous TGA/DTA analysis of Mn(II) and Fe(III) was studied from ambient temperature to 1000 $^{\circ}\text{C}$ in nitrogen atmosphere using $-\text{Al}_2\text{O}_3$ as reference. An analysis of the thermogram of the complexes indicated that Mn(II) complexes of ligand L_5 (Fig.1) shows two step decomposition. The first weight loss 5.66%, in

between temp. 60-130°C could be correlated with the loss of two lattice water (calcd 6.14 %). The anhydrous compound does not remain stable at higher temperature, it undergoes rapid decomposition in the range 130-650°C, with 80.89 % mass loss corresponds to decomposition of the complex (calcd. 81.75%) in second step. The decomposition is completed leading to the formation of stable residue of metal oxide MnO obs. 11.32 % (calcd. 12.09 %). In TG curve of Fe(III) complex of ligand L₅ (Fig.2) shows two step decomposition. The first weight loss 5.78%, in between temp. 75-180°C could be correlated with the loss of two lattice water (calcd 6.13 %). The anhydrous compound does not remain stable at higher temperature, it undergoes rapid decomposition in the range 180-585°C, with 65.51 % mass loss corresponds to decomposition of the complex (calcd. 66.67%) in second step. The decomposition is completed leading to the formation of stable residue of metal oxide Fe₂O₃ obs. 26.97 % (calcd. 27.19 %). The kinetic and thermodynamic viz the energy of activation (E_a), frequency factor (Z), entropy change (-ΔS) and free energy change (ΔG) for the non-isothermal decomposition of complexes have been determined by employing Horowitz-Metzger method [24] values are given in Table 3. The Calculated values of the given activation energy of the complexes are relatively low, indicating the autocatalysis effect of metal ion on the thermal decomposition of the complex. The negative value of

activation entropy indicates that the activated complexes were more ordered than the reaction was slow. The more ordered nature may be due to the polarization of bonds in the activated state, which might occur through charge transfer transitions [25].

Magnetic measurements and electronic absorption spectra

The electronic absorption spectrum of the L₅ Mn(II) complexes shows bands at 13477 cm⁻¹ and 24875 cm⁻¹ are assigned to ⁶A_{1g} ⁴T_{2g} and charge transfer transitions. The Mn(II) complexes were paramagnetic in nature indicates octahedral geometry[26,27]. The electronic absorption spectrum of the L₅ Fe(III) complexes shows bands at 29239 cm⁻¹. These transitions may be assigned to charge transfer transitions. The Fe(III) complexes were paramagnetic in nature indicates octahedral geometry[28-30]. All the Mn (II) and Fe (III) complexes were paramagnetic in nature.

Molar Conductivity Measurements

The metal Mn(II) and Fe(III) complexes were dissolved in DMSO and the molar conductivity of 10⁻⁴M of their solution at room temperature was measured. The lower conductance values of the complexes support their non-electrolytic nature of the compounds.

Table 1. Physical characterization, analytical and molar conductance data of compounds

Compound	Mol.Wt.	M.P. Decomp temp. °C	Colour	μ _{eff} B.M.	Molar Conduc. Mho. Cm ² mol ⁻¹
L ₅	247.68	142	White	--	----
Mn-L ₅	586.33	>300	Brown	4.57	61.82
Fe-L ₅	587.24	>300	Brown	7.70	51.30

Table 2. Elemental Analysis of Mn(II) and Fe(III) Complex:-

Compound	Found (Calculated)			
	C	H	N	M
L ₅	58.18 (58.18)	4.07 (4.07)	16.97 (16.97)	-
Mn-L ₅	49.16 (49.10)	4.12 (4.00)	14.33 (14.20)	9.36 (9.25)
Fe-L ₅	49.08 (49.00)	4.11 (4.04)	14.31 (14.10)	9.51 (9.40)

Powder x-ray diffraction

The x-ray diffractogram of Mn(II) and Fe(III) complexes of L₅ was scanned in the range 20-80° at wavelength 1.540 Å (Fig.3,4). The diffractogram and associated data depict the 2θ value for each peak, relative intensity and inter-planar spacing (d-values). The diffractogram of Mn(II) complex of L₅ had ten

reflections with maxima at 2θ = 6.63° corresponding to d value 6.65Å. The diffractogram of Fe(III) complex of L₅ had thirteen reflections with maxima at 2θ = 6.60° corresponding to d value 6.69Å. The x-ray diffraction pattern of these complexes with respect to major peaks of relative intensity greater than 10% has been indexed by using computer programmed [31]. The above indexing method also yields Miller indices (hkl),

unit cell parameters and unit cell volume. The unit cell of Mn(II) complex of L₃ yielded values of lattice constants, a= 9.45Å, b=10.32 Å, c = 17.44 Å and unit cell volume V=1700.81853 Å³. In concurrence with these cell parameters, the condition such as a b c and = = =90⁰ required for sample to be orthorhombic were tested and found to be satisfactory. Hence it can be concluded that Mn(II) complex has orthorhombic crystal system. The unit cell of Fe(III) complex of L₅ yielded values of lattice constants, a=10.21 Å, b=9.99Å, c = 19.21Å and unit cell volume V=1959.37953 Å³. In concurrence with these cell parameters, the condition such as a b c and = = =90⁰ required for sample to be orthorhombic. Hence it can be concluded Mn(II) and Fe(III) complex

of L₅ has orthorhombic crystal system. The experimental density values of the complexes were determined by using specific gravity method [32,33] and found to be 1.0758 and 1.0392 gcm⁻³ for Mn(II) and Fe(III) complexes respectively. By using experimental density values, molecular weight of complexes, Avogadro's number and volume of the unit cell were calculated. Number of molecules per unit cell were calculated by using equation = nM/NV and was found Mn(II) and Fe(III) complexes respectively. With these values, theoretical density were computed and found to be 1.0648 and 1.0282 gcm⁻³ for respective complexes. Comparison of experimental and theoretical density shows good agreement within the limits of experimental error [34].

Antibacterial activity

Antifungal activity and Antibacterial activity of ligand and metal complexes were tested *in vitro* against fungal such as *Aspergillus niger*, *Penicillium chrysogenum*, *Fusarium moneliforme*, *Aspergillus flavus* and bacteria such as *E. Coli*, *B.Subtilis*, *S. aureus* And *Bacillus subtilis* by paper disc plate method

[35-38] The compounds were tested at the concentrations 1% and 2% in DMSO and compared with known antibiotics *viz* *Griseofulvin* and *Penicillin*. (Table 4 and 5)., it is found that the inhibition by metal chelates is higher than that of a ligand and results are in good agreement with previous findings with respect to comparative activity of free ligand and its complexes [39]

Figure 5. Structure of ligand

Figure 6. The proposed Structure of the complexes
When M= Mn(II) and Fe(III).

Conclusion

In the light of above discussion we have proposed octahedral geometry for Mn(II) and Fe(III) complexes. On the basis of the physico-chemical and spectral data discussed above, one can assume that the ligand behave as dibasic, NO bidentate, coordinating via phenolic oxygen and imino nitrogen as illustrated in Fig.6. The complexes are biologically active and show enhanced antimicrobial activities compared to free ligand. Thermal study reveals thermal stability of complexes. The X-ray study suggests monoclinic crystal system for Mn(II) and Fe(III) complexes.
